Web Programming — how this course works

Assoc. Prof. Dr. Emre Akadal · Istanbul University · Faculty of Economics, MIS · Fall 2026

By the end of this term you will have a working system on a public repository, runnable by a stranger with one command, and a commit history that proves you built it week by week. That is the deliverable. Not a folder of exercises — a system you can hand to someone.

However, that sentence contains the price, and you should read it twice: **week by week.** I can see commit dates. A repository that appears in a single heroic weekend in January tells me exactly what happened, and it will be graded as what it is.

The course

Course code	YBSB3001 · 5th semester · compulsory
Credits	2 national / 5 ECTS
Contact hours	3 per week — 1 theory + 2 practice, taught as 40+40+40 minutes with two breaks
Language	English
Attendance	70%
Before class	Nothing to read

The project: an Alumni Tracking System

Everything you build this term goes into one system. The core features are mine — I set the requirements every project must meet. Everything else is yours: the data model, the language, the database, the interface, the naming, the structure. You are not choosing *what* to build. You are choosing *how*, and every week you defend that choice in front of working code.

One rule that starts in week one and never stops: **the system must come up with a single command.**

```
docker compose up
```

It does not have to work in week one. It is the target you build toward, and it is how I will run your project when I grade it.

The repository

One repository, public, named exactly `alumni` — `github.com/<your-username>/alumni`. You keep it for all fourteen weeks and you submit its link through Google Classroom.

How a week works

One slide. One mechanism. One task.

Each session I explain a single mechanism, and then you build something with it while I am in the room. That is the whole format. There is no reading list and no extra resource pack, because the mechanisms we use are fixed and you will meet each one here first. If you want to arrive already knowing what is coming, look it up — nothing is hidden.

The thing I will not do is type for you. The assistant writes syntax; you own the intent, the architecture, and every bug that ships. Nobody in this course is graded on typing speed, and nobody gets credit for code they cannot defend.

The fourteen weeks

Week	Topic
01	Project inception & fundamentals
02	Routing — the doors of the system
03	HTTP methods & CRUD
04	MVC architecture
05	Database & ORM
06	Database integration
07	Relational data & advanced routing
08	*Midterm — code review*
09	Middleware — the bouncer
10	Views & front-end integration
11	Authentication & authorization
12	Service layers
13	Deployment & CI/CD
14	*Final presentations — system handover*

What you need

Google Classroom is the only channel. Announcements, submissions and tracking all happen there. Open your university mail at `ogr.iu.edu.tr`, install Classroom, and join with the code given in the first session.

An AI assistant is mandatory; the brand is not. The cheapest route is Antigravity. If you are willing to pay, Kimi or Codex. Any other assistant is fine. None is not — this course assumes you have one.

A back-end language and a database, chosen by you. You pick them in the first session, you say out loud why, and you name one thing each of them is bad at. Then you live with the choice for fourteen weeks.

While we are here: HTML is not a programming language. It is markup — it describes, it does not decide. Everything that decides lives on the other side of the boundary, and that is where this course lives.

Grading

- **Every week leaves at least one commit.** I read the dates.
- **Midterm: your repository** — graded on how far the project has come.
- **Final: a written exam, plus the repository.**
- Faculty weights: 40% midterm, 60% final.

Let me be direct about why the commit history carries this much weight. In a course where an assistant can produce a working file in thirty seconds, the finished artifact proves very little on its own. What it cannot fake is a fourteen-week trail of small decisions, each one built on the last. That trail is the thing I am actually grading, and it is also the only part of this you will still have in five years.

Week 1

Five things, and none of them is code — the details are in the week 1 document. In short: mail and Classroom, your language and database, your assistant, the `alumni` repository, and a README that says what the system is and how to run it.

That is the whole contract. Bring a machine you can work on, pick your stack in the first session without agonising over it, and commit something every single week.

See you in week 02 — and may your routes be clean and your containers come up on the first try.
